Dear Disney Recruitment Team,

I am applying for the Product Software Engineer I role because Disney is the company where I hope to build a long-term career. I would love the opportunity to contribute the engineering experience I have developed while continuing to expand my software skills within an organization that brings technology, engineering, and creativity together. One day I hope to bring what I will learn at Walt Disney Entertainment to Walt Disney Imagineering.

At Proteor and Filament Innovations, I owned product development from initial requirements and design direction through vendor sourcing, manufacturing, production, and after-sales support. My responsibilities extended across CAD and mechanical design, electrical systems, embedded firmware, and integrating cloud-connected software. Giving me experience developing and supporting complete systems rather than working within only one engineering discipline.

A significant part of my work has also involved developing internal software and automation to eliminate manufacturing bottlenecks and improve reliability. For production deployment and version control, I created a GitHub-based system containing the configuration and firmware for multiple generations of our products. During manufacturing, a technician connects to the machine through SSH and executes a single Python command. The remaining configuration, deployment, and verification processes are automated with status information returned directly through the technician's terminal.

I also developed ExtrusionStudio, a LabVIEW-based data acquisition and processing application used within our filament manufacturing operations. The system communicates with three networked devices over Modbus, collecting measurements from nine laser sensors every 15 milliseconds to monitor extrusion diameter and visualize production tolerances. I designed the supporting network infrastructure as well, including the locally isolated VLAN and static addressing used by the equipment. The application is deployed as part of the production environment and automatically initializes and connects to the measurement hardware when the workstation starts.

Outside of work, I enjoy experimenting with technologies beyond those required by my position. My home lab includes a Proxmox server for ISO testing and a small Kubernetes cluster that I use to deploy services and experiment with networking and containerized applications. More recently, I built RileyBeenders.com, an interactive portfolio designed around structured career data rather than a traditional static resume. I am currently developing its next version, which incorporates AI agents and agent-specific skills that can interpret my previous experience against individual job postings. Along with the custom agents, new sections to the website with detailed work displaying my previous projects in more information and technical details.

What interests me most about this position is the opportunity to take the practical software, infrastructure, automation, and troubleshooting experience I have developed as a multidisciplinary engineer and apply it within a dedicated software engineering organization. I want to continue learning technologies such as AWS, Spark, Kafka, and Snowflake while contributing the systems-level perspective and ownership mentality I have developed from my current experience.

Thank you for considering me for the opportunity to help engineer Disney's next chapter. I do apologize for the long cover letter, but I have had a very interesting career path so far. I would love to welcome the opportunity to discuss how my cross-disciplinary engineering background, software experience, and desire to build a career at Disney could contribute to this team!

With curiosity,

Riley Beenders
